1.

For which of the following problems would anomaly detection be a suitable algorithm?

- [x] From a large set of primary care patient records, identify individuals who might have unusual health conditions.

Correct
Since you are just looking for unusual conditions instead of a particular disease, this is a good application of anomaly detection.

- [x] In a computer chip fabrication plant, identify microchips that might be defective.

Correct
The defective chips are the anomalies you are looking for by modeling the properties of non-defective chips.

- [ ] From a large set of hospital patient records, predict which patients have a particular disease (say, the flu).

Un-selected is correct

- [ ] Given data from credit card transactions, classify each transaction according to type of purchase (for example: food, transportation, clothing).

Un-selected is correct

Anomaly Detection

Quiz, 5 questions

5/5 points (100%)

Suppose you have trained an anomaly detection system that flags anomalies when $p(x)$ is less than ε, and you find on the cross-validation set that it has too many false positives (flagging too many things as anomalies). What should you do?

- [x] Decrease ε

Correct
By decreasing ε, you will flag fewer anomalies, as desired.

- [ ] Increase ε

3.
Suppose you are developing an anomaly detection system to catch manufacturing defects in airplane engines. You model uses

$$p(x) = \prod_{j=1}^{n} p(x_j; \mu_j, \sigma_j^2).$$

You have two features x_1 = vibration intensity, and x_2 = heat generated. Both x_1 and x_2 take on values between 0 and 1 (and are strictly greater than 0), and for most "normal" engines you expect that $x_1 \approx x_2$. One of the suspected anomalies is that a flawed engine may vibrate very intensely even without generating much heat (large x_1, small x_2), even though the particular values of x_1 and x_2 may not fall outside their typical ranges of values. What additional feature x_3 should you create to capture these types of anomalies:

- [x] $x_3 = \frac{x_1}{x_2}$

Correct
This is correct, as it will take on large values for anomalous examples and smaller values for normal examples.

- [ ] $x_3 = x_1^2 \times x_2$
- [ ] $x_3 = x_1 + x_2$
- [ ] $x_3 = x_1 \times x_2$

Anomaly Detection

Quiz, 5 questions

5/5 points (100%)

If you have a large labeled training set with many positive examples and many negative examples, the anomaly detection algorithm will likely perform just as well as a supervised learning algorithm such as an SVM.

Un-selected is correct

If you do not have any labeled data (or if all your data has label $y = 0$), then is is still possible to learn $p(x)$, but it may be harder to evaluate the system or choose a good value of ϵ.

Correct
Only negative examples are used in training, but it is good to have some labeled data of both types for cross-validation.

When choosing features for an anomaly detection system, it is a good idea to look for features that take on unusually large or small values for (mainly the) anomalous examples.

Correct
These are good features, as they will lie outside the learned model, so you will have small values for $p(x)$ with these examples.

If you are developing an anomaly detection system, there is no way to make use of labeled data to improve your system.

Un-selected is correct

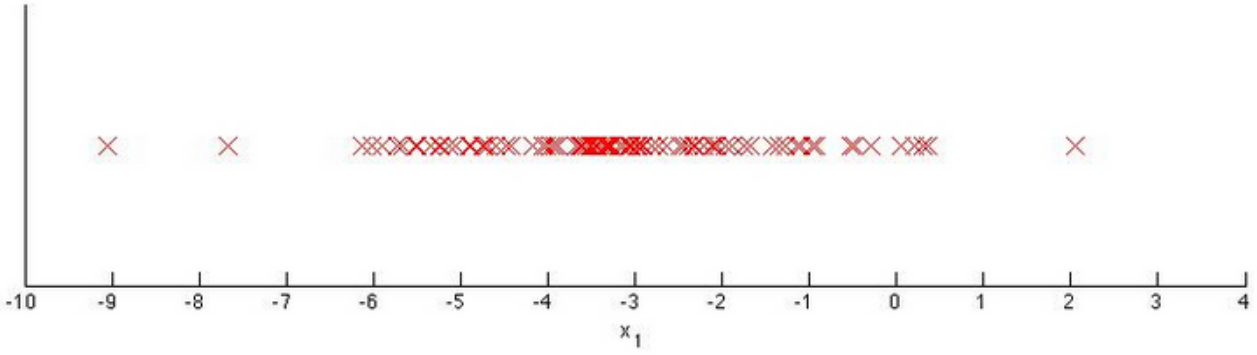
Anomaly Detection

Quiz, 5 questions

5/5 points (100%)

You have a 1-D dataset $\{x^{(1)}, \ldots, x^{(m)}\}$ and you want to detect outliers in the dataset. You first plot the dataset and it looks like this:



Suppose you fit the gaussian distribution parameters μ_1 and σ_1^2 to this dataset. Which of the following values for μ_1 and σ_1^2 might you get?

- [x] $\mu_1 = -3, \sigma_1^2 = 4$

Correct

This is correct, as the data are centered around -3 and tail most of the points lie in [-5, -1].

- [ ] $\mu_1 = -6, \sigma_1^2 = 4$
- [ ] $\mu_1 = -3, \sigma_1^2 = 2$
- [ ] $\mu_1 = -6, \sigma_1^2 = 2$
